- 10 Conclusions

Introduction

- **Semantic Web**

- Aims at making information available in a form that is understandable by machines
- Web Ontology Language (OWL)
 - Based on Description Logics

- **Reasoners**

- Most DL reasoners use a tableau algorithm for doing inference
- Most of them are implemented in a procedural language
 - Example: Pellet, RacerPro, FaCT++

Uncertainty Representation

- **Semantic Web**

- Incompleteness or uncertainty are intrinsic of much information on the World Wide Web
- Most common approaches: probability theory, Fuzzy Logic

- **Logic Programming**

- Uncertain relationships among entities characterize many complex domains
- Most common approach: probability theory → **Distribution Semantics** [Sato, 1995].
 - It underlies many languages (ICL, PRISM, ProbLog, LPADs),...
 - They define a probability distribution over normal logic programs, called worlds
 - The distribution is extended to a joint distribution over worlds and queries
 - The probability of a query is obtained from this distribution by summing out worlds

DISPONTE: DIstribution Semantics for Probabilistic ONTologiEs

- Idea: **annotate axioms of an ontology with a probability** and assume that the axioms are pairwise independent

$$0.6 :: \textit{Cat} \sqsubseteq \textit{Pet}$$

- A probabilistic ontology defines thus a distribution over normal theories (worlds) obtained by including an axiom in a world with a probability given by the annotation

DISPONTE

- **Atomic choice**: a pair (E_i, k) , where E_i is the i th probabilistic axiom and $k \in \{0, 1\}$ indicates whether E_i is chosen to be included in a world ($K = 1$) or not ($K = 0$).
- **Selection** σ : set of one atomic choice for each probabilistic axiom.
- σ identifies a **world** w_σ
- $P(w_\sigma) = \prod_{(E_i, 1) \in \sigma} p_i \prod_{(E_i, 0) \in \sigma} (1 - p_i)$
- Probability of a query Q given a world w : $P(Q|w) = 1$ if $w \models Q$, 0 otherwise
- Probability of Q

$$P(Q) = \sum_w P(Q, w) = \sum_w P(Q|w)P(w) = \sum_{w:w \models Q} P(w)$$

Inference and Query answering

- The probability of a query Q can be computed according to the distribution semantics by first finding the explanations for Q in the knowledge base
- **Explanation**: subset of axioms of the KB that is sufficient for entailing Q
- All the explanations for Q must be found, corresponding to all ways of proving Q
- Probability of $Q \rightarrow$ probability of the DNF formula

$$F(Q) = \bigvee_{e \in E_Q} \left(\bigwedge_{F_i \in e} X_i \right)$$

where E_Q is the set of explanations and X_i as a Boolean random variable associated to axiom F_i

- We exploit Binary Decision Diagrams for efficiently computing the probability of a DNF formula

BUNDLE

Binary decision diagrams for Uncertain reasoning on Description Logic theories

- BUNDLE performs inference over DISPONTE knowledge bases
- It exploits an underlying ontology reasoner able to return all explanations for a query, such as **Pellet** [Sirin et al., 2007].
- Explanations for a query in the form of *a set of sets of axioms*
- BUNDLE uses a *tableau algorithm*
- Each tableau expansion rule updates a **tracing function** τ , which associates sets of axioms with nodes and edges of the tableau

Non-determinism

- **Problem:** some tableau expansion rules are non-deterministic
 - Reasoners implement a search strategy in a or-branching space
- We want to find all the possible explanations for a query
 - The algorithm has to explore all the non-deterministic choices done

Why Prolog?

- The reasoners implemented using procedural languages have to implement also a backtracking algorithm to find all the possible explanations
 - Example: Pellet uses an hitting set algorithm that repeatedly removes an axiom from the KB and then computes again a new explanation
- Reasoners written in Prolog can exploit Prolog's backtracking facilities for performing the search

TRILL - Tableau Reasoner for description Logics in proLog

- TRILL implements the tableau algorithm using Prolog
- It resolves the axiom pinpointing problem in which we are interested in the set of explanations that entail a query
- Thea2 library for converting OWL DL ontologies to Prolog:
 - each OWL axiom is translated into a Prolog fact
- It applies all the possible expansion rules, first the non-deterministic ones then the deterministic ones
- It returns the set of the explanations

TRILL - Tableau Reasoner for description Logics in proLog

- Deterministic rules are implemented by predicates that take as input a tableau and return a new single tableau
- Non-deterministic rules are implemented by predicates that take as input a tableau and return a list of tableaux from which one is non-deterministically chosen.

TRILL^P - Tableau Reasoner for description Logics in proLog exploiting Pinpointing formula

- TRILL^P resolves the axiom pinpointing problem by computing a *pinpointing formula*
[Baader and Peñaloza, 2010a, Baader and Peñaloza, 2010b]
 - 1 We associate a Boolean variable to each axiom of the KB
 - 2 The pinpointing formula is a monotone Boolean formula on these variables that compactly encodes the set of all explanations

TRILL^P - Tableau Reasoner for description Logics in proLog exploiting Pinpointing formula

- Deterministic and non-deterministic rules are implemented in the same way of TRILL's expansion rules
- They associate a pinpointing formula to the labels of the nodes instead of a set of explanations

Computing the probability

- The pinpointing formula is a Boolean formula which can be directly translated into a BDD
- We can compute the probability of the query from the BDD as in BUNDLE

TRILL^P - Tableau Reasoner for description Logics in proLog

- Example

$$F_1 = \text{fluffy} : \text{Cat}$$

$$F_2 = \text{tom} : \text{Cat}$$

$$0.6 :: F_3 = \text{Cat} \sqsubseteq \text{Pet}$$

$$0.5 :: F_4 = \exists \text{hasAnimal.Pet} \sqsubseteq \text{NatureLover}$$

$$F_5 = (\text{kevin}, \text{fluffy}) : \text{hasAnimal}$$

$$F_6 = (\text{kevin}, \text{tom}) : \text{hasAnimal}$$

- Let $Q = \text{kevin} : \text{NatureLover}$ be the query,
- the set of explanations is $\{\{F_5, F_1, F_3, F_4\}, \{F_6, F_2, F_3, F_4\}\}$,
- the pinpointing formula is $((F_5 \wedge F_1) \vee (F_6 \wedge F_2)) \wedge F_3 \wedge F_4$.
- the probability is $P = 0.3$

A Web Interface for TRILL: TRILL-on-SWISH

- SWISH [Lager and Wielemaker, 2014]
 - a recently proposed Web framework for logic programming
 - based on various features and packages of SWI-Prolog
 - allows the user to write Prolog programs and ask queries in the browser
- **TRILL-on-SWISH** allows users to write a KB in the RDF/XML format directly in the web page or load it from a URL, and specify queries that are answered by TRILL running on the server.
- Available at <http://trill.lamping.unife.it>.

Experiments

- Comparison between TRILL, TRILL^P and BUNDLE
- We consider four datasets:
 - 1 BRCA that models the risk factor of breast cancer;
 - 2 An extract of DBPedia;
 - 3 Biopax level 3 that models metabolic pathways;
 - 4 Vicodi that contains information on European history.

Table : Average time for computing the probability of queries in seconds.

DATASET	TRILL TIME (S)	TRILL ^P TIME (S)	BUNDLE TIME (S)
BRCA	27.87	4.74	6.96
DBPedia	51.56	4.67	3.79
Biopax level 3	0.12	0.12	1.85
Vicodi	0.19	0.19	1.12

Conclusions

- We presented a semantics for modeling probabilistic DL KBs
- We presented three reasoners which can compute the probability of queries under the DISPONTE semantics
- We presented a web interface for TRILL, one of the reasoners presented in the paper
- The results we obtained show that:
 - ① Prolog is a viable language for implementing DL reasoning algorithms
 - ② TRILL's and TRILL^P's performances are comparable with those of a state-of-art reasoner

Thanks.
